0.1 `model.frame.multiple`: Extracting the "environment" of a model formula

Description

Use `model.frame.multiple` after `parse.par` to create a data frame of the unique variables identified in the formula (or list of formulas).

Usage

```
model.frame.multiple(formula, data, eqn = NULL, ...)
```

Arguments

`formula`	a list of formulas of class `"multiple"`, returned from `parse.par`
`data`	a data frame containing all the variables used in `formula`
`eqn`	an optional character string or vector of character strings specifying the equations (specified in `describe.mymodel`) for which you would like to pull out the relevant variables.
`...`	additional arguments passed to `model.frame.default`

Value

The output is a data frame (with a terms attribute) containing all the unique explanatory and response variables identified in the list of formulas. By default, missing (`NA`) values are listwise deleted.

If `as.factor` appears on the left-hand side, the response variables will be returned as an indicator (0/1) matrix with columns corresponding to the unique levels in the factor variable.

If any formula contains more than one `tag` statement, `model.frame.multiple` will return the original variable in the data frame and use the `tag` information in the terms attribute only.

Examples

```
## Not run:
data(sanction)
formulae <- list(import ~ coop + cost + target,
                 export ~ coop + cost + target)
fml <- parse.formula(formulae, model = "bivariate.logit")
D <- model.frame(fml, data = sanction)
## End(Not run)
```
