

utf8

0.1 write.po: write.po.R

Description

converts template files into message files. This is mostly used to localize messages that expand large amounts of source-code.

Usage

```
zkeleton(path, from, to, lang, append, overwrite)
```

Arguments

path	a character-string specifying the path of the model to be constructed
from	a vector of character-strings specifying the files to encode as a po file
to	a character string specifying the name of the po file. Should end in <code>"/R-en.po"</code>
lang	a 2-letter character string specifying the language code of the message to be encoded
append	a boolean value specifying whether the file should overwrite any existin po file

Details

write.po is a tool for developers to create po files in a variety of languages from zelig-style template files

Value

nothing.

Note

write.po is a fairly clumsy implementation to handle the arduous process of encoding R-like language into po files. Without this, zkeleton-style message strings would be nearly impossible for non-technical users to implement. That is, it removes the necessity for users to understand the subtleties of msgfmt, gettext, et cetera.
